Prozeduren: Numerische, inverse Laplace-Transformation (Talbot), für t nicht 0 eingeben

```
# Talbot suggested that the Bromwich line be deformed into a contour that begins
# and ends in the left half plane, i.e., z ? -8 at both ends.
# Due to the exponential factor the integrand decays rapidly
# on such a contour. In such situations the trapezoidal rule converge
# extraordinarily rapidly.
# For example here we compute the inverse transform of F(s) = 1/(s+1) at t = 1
#-----
#Octave:
#>> pkg load symbolic
#>> syms s
#>> F=1/(s+1)
#F = (sym)
#
# 1
# -----
# s + 1
#
#>> error=talbot(function_handle(F),1,24)-exp(-1)
#ans =  1.6098e-015
#-----
#
# Talbot method is very powerful here we see an error of 1.61e-015
# with only 24 function evaluations

#
# Shift contour to the right in case there is a pole on the positive real axis : Note the contour will
# not be optimal since it was originally developed for function with
# singularities on the negative real axis
# For example take F(s) = 1/(s-1), it has a pole at s = 1, the contour needs to be shifted with one
# unit, i.e shift = 1. But in the test example no shifting is necessary
```
